

React : The Big Picture

Monday, 8 October 2018

7:41 PM

- Good Source: <https://app.pluralsight.com/library/courses/react-big-picture/table-of-contents>
-
- Each React component is a separate concern.
- **React Native** is a related library to react used to make native ios and android apps.
- React was developed by facebook and then open sourced.
- JSX used by React is an HTML-like language that compiles to JavaScript.
- React's virtual DOM improves performance by minimizing DOM changes.

Why React

- **Flexibility:** rendering is separated from react. Can be used to make a variety of things like web apps, native mob apps, desktop apps, etc. <https://github.com/chentsulin/awesome-react-renderer>
- **Developer Experience:**
 - Uses HTML inside JS (opposite of other frameworks like angular, vue.js etc.) which instead of making HTML powerful and making you learn their methods you use power of JS.
 - Also after every save changes are reflected in browser.
 - Whenever facebook has made a breaking change in react it gave a **codemod** to update your code.
- **Performance:** Updates **using Virtual DOM** which is highly effective.
- **Testability:** It makes testing front end easy . Tries to use **Pure Functions**.

	Traditional UI tests	React
•	Hassle to set up	Little to no config required
	Requires browser	Run in-memory via Node
	Slow	Fast
	Brittle integration tests	Reliable, deterministic unit tests

Time-consuming to write, maintain

Write quickly, update easily

Trade Offs:

Framework

1.

Clear opinions
Less decision fatigue
Less setup overhead
More cross-team consistency

Library

Facebook
slowly replaced
their PHP app
with React

Light-weight
Sprinkle on existing apps

2.

Two-way binding

Less coding
Automatic

```
let user = 'Cory';
```

```
<input  
  type="text"  
  value={user}  
/>
```

One-way binding

More control
More explicit
Easy to debug

```
state = { user: 'Cory' };
```

```
function handleChange(event) {  
  this.setState({  
    user: event.target.value  
  });  
}
```

```
<input  
  type="text"  
  value={this.state.user}  
  onChange={this.handleChange}  
/>
```

3. Uses HTML inside JS (opposite of other frameworks like angular, vue.js etc.) which instead of making HTML powerful and making you learn their methods you use power of JS.

4.

Separate
technologies,
but *intertwined*
concerns.

Each *component* is a separate concern.

Benefit of React's single file approach:

You can read, understand, and work with each autonomous file in isolation.

React Disadvantages & solutions.

- **HTML and JSX differ:** **JSX** is 99% HTML. Only 4-5 line differences. We also have online convertors for it.
- **Build Step Required:** Build Step is required to convert JSX to JS. This does not matter now as every framework uses it.
- **IMPORTANT: Version Conflicts:** 2 version of react cannot run at same time on same page or else will lead to version conflict as it uses **Runtime**. So need to keep react component at same version. Also needs to run compatible versions of other react libraries. Also easy to upgrade using facebook's **codemon** libraries.
- **Outdated Resources:** Online sources come in react searches are for older version and outdated content creates problem.
- **Decision Fatigue:** Many options creates confusion. Main decisions to be taken:
 - **Dev Environment** (recommended use: **create-react-app**)
 - **ES class or createClass** (ES class recommended as is latest)
 - **Types** (recommended: **proptypes** over typescript or flow unless you need typesafety)
 - **State** (mostly new libraries not needed. **Redux** can be used.)
 - **Styling** (use Traditional CSS to start).
